ABSTRACT

The main objective of cluster analysis is the statistical technique of identifying data points and assigning them into meaningful clusters. The purpose of this paper is to compare different types of clustering algorithms to find the clustering algorithm that performs the best for varying complexities in Gaussian data. The clustering algorithms used would include: Partitioning Around Medoids (PAM), K-means, Hierarchical with different linkages (Ward's linkage, Single linkage, Complete linkage, Average linkage, McQuitty's method, Gower's method, and Centroid method). The different types of complexities would include different number of dimensions, average pairwise overlap between clusters, number of points simulated from each cluster. After the data is simulated the Adjusted Rand Index will be used gauge the performance of the clusters. From that a t-test will also be used to see if there are any clustering algorithms that as well as other clustering algorithms.

ACKNOWLEDGEMENTS

I am very grateful to all of those who assisted me in completing this paper. I would like to thank Dr. Rhonda Magel for her patience and guidance. I think she is one of the greatest instructors of the Statistics Department with her ability to make difficult course material understandable and her willingness to help provide students with a great learning environment.

Thank you to Dr. Seung Won Hyun, and Dr. Kenneth Magel for being on my committee. I am also extremely grateful for the opportunity to learn Statistics at North Dakota State University. I would like to thank all of my teachers for the great foundation and useable knowledge they have taught me about Statistics. I would also like to thank Dr. Fu Chih Cheng and Dr. Volodymyr Melnykov for introducing me to cluster analysis and making such a difficult topic understandable and a subject that I wanted to learn more about and do research on. I would also like to thank my Mom and Dad for the love and support that they have given me. College has turned out to be a long journey, and they have encouraged me the whole way.

CHAPTER 1. INTRODUCTION

Which clustering algorithm is the best? Which clustering should you use if your data is Gaussian? These are both good questions to which there is no clear answer. There are many different uses of clustering algorithms which can be used in many different applications. Some of these applications may be comparable to finding patterns in web users, finding common items people purchase at grocery stores, or finding common items people purchase from Amazon.com to recommend other items they should buy. Companies spend a substantial amount of money to have their website come up first on a Google search. If you know the time or a pattern of when your customers are searching for your product you can make sure you are at the top of the search list. If you have a digital image there are many different things you can do with this image such as use clustering to recognize the person and have the computer label that person's name for all other pictures in which they are present. This could also be useful to the government in identifying criminals in public where a camera is present. Clustering is also very popular in market research, separating customers into useful groups where companies would be interested in marketing a specific product to increase profit on an otherwise not so common item. Another example may be mailing a flyer for a big up-coming sale where it is not cost effective to mail a flier to all previous customers because of the expensive. One could use cluster analysis to decide upon a group of people to receive the flier.

There are many components to account for in cluster analysis. Some clustering algorithms perform better than others, depending on the data set. When considering which clustering algorithms work more efficiently for the most common type of data, Gaussian, one needs to know which cluster algorithms perform the best? Which clustering algorithm performs the best when there is very little overlap between the clusters? Which clustering algorithm

perform the best when there is a substantial amount of overlap between clusters? In addition to overlap, other components to consider while conducting clustering analysis include the number of clusters and the number of dimensions. As these components are changed, does the best algorithm change?

CHAPTER 2. REVIEW OF LITERATURE

There are many different clustering algorithms. Some clustering algorithms are used exclusively for certain types of data. Most clustering algorithms can be categorized into one of the following categories: partitioned, model-based parametric, or hierarchical.

Partitioned clustering works by compartmentalizing the data into separate clusters. This is typically done by using some sort of a centroid (geometric center) and assigns the data to each centroid while maximizing the dissimilarity between clusters. One popular partitioning clustering algorithm is the K-means algorithm.

Model-based parametric clustering is another approach which assumes a common trait to help with clustering. In this approach, the data is assumed to come from a mixture model for probability distributions. Where the number clusters would be the number of mixture components. The expectation maximization algorithm is typically used in this method to find the mixing proportions along with the parameters for each of the mixture models.

One specific type of cluster analysis is hierarchical clustering. There are two types of hierarchical clustering: agglomerative and divisive. Agglomerative begins with each data point being its own cluster, than successively merges two clusters together until there is only one cluster. Divisive is the opposite of agglomerative. It begins with all the data as one cluster then, based on the linkage function, splits one cluster into two clusters. The splitting of clusters process repeats until all points are their own cluster. Hierarchical clustering algorithms are usually defined by the linkage function. Both methods are based on the linkage function, either the splitting or combining of clusters. The linkage function defines the rule by which the distance between clusters is measured. Hierarchical clustering has a unique hierarchy structure with which

to combine or separate one cluster per step. This structure is easily seen using a dendrogram, which is a tree structure showing how the points are grouped.

2.1. Hierarchical Clustering with Single Linkage

The single linkage method is an agglomerative method, meaning every point starts out as a cluster, then each step up two clusters are combined to form a new cluster. The single linkage method is calculated by first taking the Euclidean distance between all the pair data points. Then two points (or clusters) with smallest distance from each other are combined to form a cluster. At each step, the clusters with the smallest distance is combined to form a cluster. This process is then repeated until there is only one cluster. For example, consider the following data:

Table 2.1

List of the Data

Point	X	Y
Point 1	1.75	2.5
Point 2	1.85	3.0
Point 3	1.90	1.8
Point 4	1.95	2.3
Point 5	2.00	2.2

The purpose of the data is to show the calculations from a step by step basis.

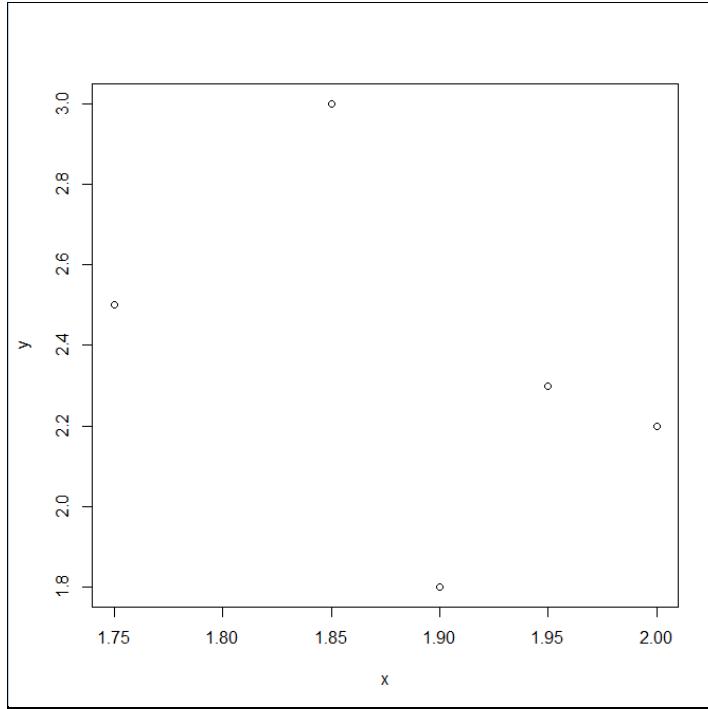

Figure 1.1. Plot of the Data.

We now have to calculate the Euclidean distance between all of the pairs of points. The distance between the i -th and j -th point is calculated as follows:

Equation 2.1 Distance Function for Euclidean Distance

$$d(x_i, x_j) = \sqrt{(x_i - x_j)^2 + (y_i - y_j)^2} \quad (2.1)$$

For simplicity, this can be arranged into a matrix of distances between each pair of points.

Table 2.2

List of the Distance Matrix

Distance	Point2	Point3	Point4	Point5
Point1	0.51	0.7159	0.2828	0.3905
Point2		1.201	0.7071	0.8139
Point3			0.5025	0.4123
Point4				0.4123

Looking at the distance matrix, we would combine clusters 4 and 5 together. Since we are using the single linkage from this point forward, we will use the minimum distance between the clusters if there is more than one point in a cluster (Gan, Ma, & Wu, 2007, p. 118). The calculations are then made as follows:

$$D(\{Point4, Point5\}, Point1)$$

$$= \text{Min}(\{D(Point4, Point1)\}, \{D(Point5, Point1)\})$$

$$= \text{Min}(0.2828, 0.3905)$$

$$= 0.2828$$

$$D(\{Point4, Point5\}, Point2)$$

$$= \text{Min}(\{D(Point4, Point2)\}, \{D(Point5, Point2)\})$$

$$= \text{Min}(0.7071, 0.8139)$$

$$= 0.7071$$

$$D(\{Point4, Point5\}, Point3)$$

$$= \text{Min}(\{D(Point4, Point3)\}, \{D(Point5, Point3)\})$$

$$= \text{Min}(0.5025, 0.4123)$$

$$= 0.4123$$

Table 2.3

Distance Matrix Single Combine Point {4,5}

Distance	Point2	Point3	{Point4,Point5}
Point1	0.51	0.7159	0.2828
Point2		1.201	0.7071
Point3			0.4123

The two closest clusters are the Point 1 and {Point 4, Point 5}. We combine these two clusters into one cluster and recalculate the distance matrix.

$$D(\{Point1, Point4, Point5\}, Point2)$$

$$= \text{Min}(D(\{Point4, Point5\}, Point2), D(Point1, Point2))$$

$$= \text{Min}(0.7071, 0.51)$$

$$= 0.51$$

$$D(\{Point1, Point4, Point5\}, Point3)$$

$$= \text{Min}(D(\{Point4, Point5\}, Point3), D(Point1, Point3))$$

$$= \text{Min}(0.4123, 0.7159)$$

$$= 0.4123$$

Table 2.4

Distance Matrix Single Combine Point {1,4,5}

Distance	Point3	{Point 1, Point4, Point5}
Point2	1.201	0.51
Point3		0.4123

The smallest distance is 0.4123, so combining Point 3 with {Point 1, Point 4, Point 5} to form a cluster. We recalculate the distance matrix. There are only two clusters left we know that they will be combined in the last step. The calculation is as follows.

$$D(\{Point1, Point3, Point4, Point5\}, Point2)$$

$$= \text{Max}(D(\{Point1, Point4, Point5\}, Point2), D(Point3, Point2))$$

$$= \text{Max}(0.51, 1.201)$$

$$= 0.51$$

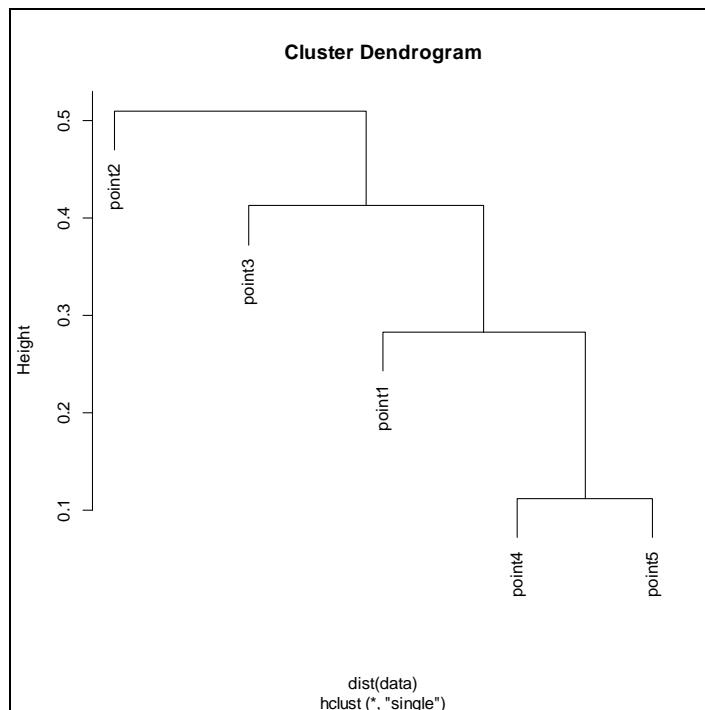

Figure 2.2. Dendrogram for the Single Linkage Method.

Looking at this figure, we can see that we first combined the points 4 and 5 into a cluster.

Then as the height gets bigger we connect more points to the cluster.

2.2. Hierarchical Clustering with Average Linkage

The average linkage method is calculated by first taking the Euclidean distance of all pairs of data points. Merge the two points with the minimum distance. Next, take the average distance between each pair of clusters and merge the two clusters with the smallest average distance. This process is then repeated, until there is only one cluster.

Using the example data, we first combine points 1 and 5 since they are the closest. This then leads us to use the average distance when computing the next distance matrix. The distance between two points is then calculated as the average. Combining Point4 and Point5 since they are the smallest distance apart, we then have to calculate the distance from this cluster to the other points as follows:

$$D(\{Point4, Point5\}, Point1)$$

$$\begin{aligned} &= \left(\frac{1}{2}\right) * (D(Point4, Point1) + D(Point5, Point1)) \\ &= \left(\frac{1}{2}\right) * (0.2828 + 0.3905) \\ &= 0.3367 \end{aligned}$$

$$D(\{Point4, Point5\}, Point2)$$

$$\begin{aligned} &= \left(\frac{1}{2}\right) * D(Point4, Point2) + \left(\frac{1}{2}\right) * D(Point5, Point2) \\ &= \left(\frac{1}{2}\right) * 0.7071 + \left(\frac{1}{2}\right) * 0.8139 \\ &= 0.7605 \end{aligned}$$

$$\begin{aligned}
D(\{Point4, Point5\}, Point3) \\
&= \left(\frac{1}{2}\right) * D(Point4, Point3) + \left(\frac{1}{2}\right) * D(Point5, Point3) \\
&= \left(\frac{1}{2}\right) * 0.5025 + \left(\frac{1}{2}\right) * 0.4123 \\
&= 0.4574
\end{aligned}$$

Table 2.5

Distance Matrix Average Combine Point {4,5}

Distance	Point2	Point3	{Point4, Point5}
Point1	0.51	0.7159	0.3367
Point2		1.201	0.7605
Point3			0.4574

After combining Point 1 with Point 4 and 5, we then come up with a new distance matrix.

The calculations for this matrix are as follows:

$$\begin{aligned}
D(\{Point1, Point4, Point5\}, Point2) \\
&= \left(\frac{1}{3}\right) * (D(Point1, Point2) + D(Point4, Point2) \\
&\quad + D(Point5, Point2)) = \left(\frac{1}{3}\right) * (0.51 + 0.7071 + 0.8139) \\
&= 0.677
\end{aligned}$$

$$\begin{aligned}
& D(\{Point1, Point4, Point5\}, Point3) \\
&= \left(\frac{1}{3} \right) \\
&\quad * (D(Point1, Point3) + D(Point4, Point3) \\
&\quad + D(Point5, Point3)) = \left(\frac{1}{3} \right) * (0.7159 + 0.5025 + 0.4123) \\
&= 0.5436
\end{aligned}$$

Table 2.6

Distance Matrix Average Combine Point {1,4,5}

Distance	Point3	{Point1, Point4, Point5}
Point2	1.201	0.677
Point3		0.5436

After the calculation, combine Point 3 with Points 1, 4, 5. We have the following distance matrix:

$$\begin{aligned}
& D(\{Point1, Point3, Point4, Point5\}, Point2) \\
&= \left(\frac{1}{4} \right) * (D(Point1, Point2) + D(Point3, Point2) \\
&\quad + D(Point4, Point2) + D(Point5, Point2)) \\
&= \left(\frac{1}{4} \right) * (0.51 + 1.201 + 0.7071 + 0.8139) = 0.5436
\end{aligned}$$

Table 2.7

Distance Matrix Average Combine Point {1,3,4,5}

Distance	{Point1, Point3, Point4, Point5}
Point2	0.808

We are then left with combining Point 2 with the other points to form one large cluster (Gan, Ma, & Wu, 2007, p. 122).

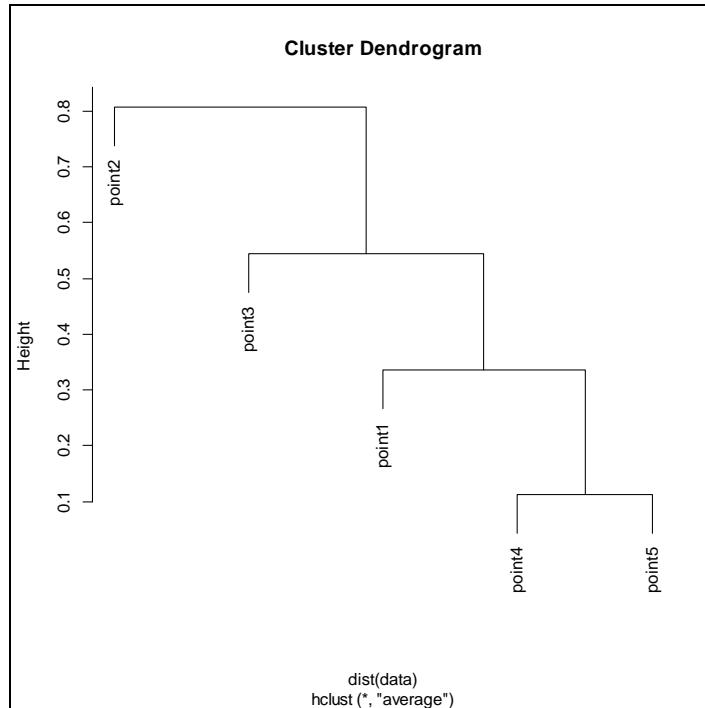

Figure 2.3. Dendrogram for the Average Linkage Method.

The dendrogram summarizes the calculations of the points that join at different distances.

2.3. Hierarchical Clustering with Centroid Linkage

The centroid method is calculated by first taking the Euclidean distance of all the pairs of data. First, combine the two closest points to form a cluster.

Equation 2.2 Distance Function for the Centroid Method

$$D(C_k, C_i \cup C_j) = \frac{n_i}{n_i + n_j} D(C_k, C_i) + \frac{n_j}{n_i + n_j} D(C_k, C_j) - \frac{n_i}{(n_i + n_j)^2} D(C_i, C_j)$$

n_k is the number of elements in cluster k

(2.2)

n_j is the number of elements in cluster j

n_i is the number of elements in cluster i

Combine Point 4 and 5 since it is the smallest distance. The distance is then calculated as follows.

$$\begin{aligned}
 & DD(\{Point4, Point5\}, Point1) \\
 &= \left(\frac{1}{2}\right) * (D(Point4, Point1) + D(Point5, Point1)) - \left(\frac{1}{4}\right) \\
 &\quad * D(Point4, Point5) \\
 &= \left(\frac{1}{2}\right) * (0.2828 + 0.3905) - \left(\frac{1}{4}\right) * 0.1118 \\
 &= 0.3087
 \end{aligned}$$

$$\begin{aligned}
 & D(\{Point4, Point5\}, Point2) \\
 &= \left(\frac{1}{2}\right) * (D(Point4, Point2) + D(Point5, Point2)) - \left(\frac{1}{4}\right) \\
 &\quad * D(Point4, Point5) \\
 &= \left(\frac{1}{2}\right) * (0.7071 + 0.8139) - \left(\frac{1}{4}\right) * 0.1118 \\
 &= 0.7326
 \end{aligned}$$

$$\begin{aligned}
 & D(\{Point4, Point5\}, Point3) \\
 &= \left(\frac{1}{2}\right) * (D(Point4, Point3) + D(Point5, Point3)) - \left(\frac{1}{4}\right) \\
 &\quad * D(Point4, Point5) \\
 &= \left(\frac{1}{2}\right) * (0.5025 + 0.4123) - \left(\frac{1}{4}\right) * 0.1118 \\
 &= 0.4295
 \end{aligned}$$

Table 2.8

Distance Matrix Centroid Combine Point {4,5}

Distance	Point2	Point3	{Point4, Point5}
Point1	0.51	0.7159	0.3087
Point2		1.201	0.7326
Point3			0.4295

Combine the points with the smallest entry which is 0.3087. After combining Point1 with Point 4 and 5, we calculate the next distance matrix as follows.

$$\begin{aligned}
 D(\{Point1, Point4, Point5\}, Point2) &= \left(\frac{2}{3}\right) * D(\{Point4, Point5\}, Point2) + \\
 &\quad \left(\frac{1}{3}\right) * D(Point2, Point1) - \left(\frac{2}{9}\right) * D(\{Point4, Point5\}, Point1) \\
 &= \left(\frac{2}{3}\right) * 0.7326 + \left(\frac{1}{3}\right) * 0.51 - \left(\frac{2}{9}\right) * 0.3087 \\
 &= 0.5898
 \end{aligned}$$

$$\begin{aligned}
 D(\{Point1, Point4, Point5\}, Point3) &= \left(\frac{2}{3}\right) * \\
 D(\{Point4, Point5\}, Point3) &+ \left(\frac{1}{3}\right) * D(Point3, Point1) - \left(\frac{2}{9}\right) * \\
 D(\{Point4, Point5\}, Point1) &= \left(\frac{2}{3}\right) * 0.4295 + \left(\frac{1}{3}\right) * 0.7159 - \left(\frac{2}{9}\right) * 0.3087 \\
 &= 0.4564
 \end{aligned}$$

Table 2.9

Distance Matrix Centroid Combine Point {1,4,5}

Distance	Point3	{Point1, Point4, Point5}
Point2	1.201	0.5898
Point3		0.4564

We combine {Point1, Point4, Point 5} with Point 3 since it has the minimum distance.

We then obtain the next distance matrix. This is consequently the last calculation so it is known that these two clusters will be combined (Gan, 126). For illustration purposes the calculation is as follows.

$$\begin{aligned}
 D(\{Point1, Point3, Point4, Point5\}, Point2) &= \left(\frac{3}{4}\right) * \\
 D(\{Point1, Point4, Point5\}, Point2) + \left(\frac{1}{4}\right) * D(Point3, Point2) - \left(\frac{3}{16}\right) * \\
 D(\{Point1, Point4, Point5\}, Point3) \\
 &= \left(\frac{3}{4}\right) * 0.5898 + \left(\frac{1}{4}\right) * 1.201 - \left(\frac{3}{16}\right) * 0.4564 \\
 &= 0.6570
 \end{aligned}$$

The dendrogram confirms our calculations and puts it in an easy to read picture.

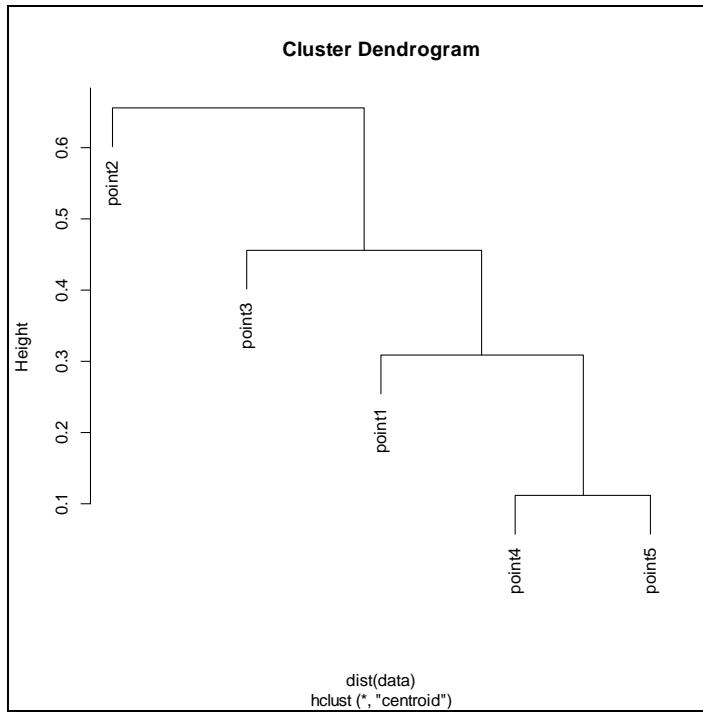

Figure 2.4. Dendrogram for the Centroid Linkage Method.

2.4. Hierarchical Clustering with Complete Linkage

The complete linkage method is calculated first, by taking the Euclidean distance of all pairs of the data. First, pair the minimum two points to form a new cluster. Then, take the maximum distance between each pair of points within the cluster we just combined. Next, merge the two points with the minimum distance. After you calculate the distance as the maximum distance between the clusters; combine the clusters with the smallest maximum distance. This process is repeated until there is only one cluster. This method is also known as the furthest neighbor; as it combines the two clusters with the closest maximum distance. Here is an example to help illustrate.

The closest distance is 0.118; we combine these two clusters. This leaves us with the following table. We must take the distance between all the points; while comparing with the max of the cluster we previously combined.

$$\begin{aligned}
D(\{Point4, Point5\}, Point1) \\
&= \text{Max}(\{D(Point4, Point1)\}, \{D(Point5, Point1)\}) \\
&= \text{Max}(0.2828, 0.3905) \\
&= 0.3905
\end{aligned}$$

$$\begin{aligned}
D(\{Point4, Point5\}, Point2) \\
&= \text{Max}(\{D(Point4, Point2)\}, \{D(Point5, Point2)\}) \\
&= \text{Max}(0.7071, 0.8139) \\
&= 0.8139
\end{aligned}$$

$$\begin{aligned}
D(\{Point4, Point5\}, Point3) \\
&= \text{Max}(\{D(Point4, Point3)\}, \{D(Point5, Point3)\}) \\
&= \text{Max}(0.5025, 0.4123) \\
&= 0.5025
\end{aligned}$$

Table 2.10

Distance Matrix Complete Point {4,5}

Distance	Point2	Point3	{Point4, Point5}
Point1	0.51	0.7159	0.3905
Point2		1.201	0.8139
Point3			0.5025

This means we would combine Point1 with {Point4, Point5}. This leads to the following distance matrix.

$$\begin{aligned}
D(\{Point1, Point4, Point5\}, Point2) \\
&= \text{Max}(D(\{Point4, Point5\}, Point2), D(Point1, Point2)) \\
&= \text{Max}(0.8139, 0.51) \\
&= 0.8139
\end{aligned}$$

$$\begin{aligned}
D(\{Point1, Point4, Point5\}, Point3) \\
&= \text{Max}(D(\{Point4, Point5\}, Point3), D(Point1, Point3)) \\
&= \text{Max}(0.5025, 0.7159) \\
&= 0.7159
\end{aligned}$$

Table 2.11

Distance Matrix Complete Point {1,4,5}

Distance	Point3	{Point1, Point4, Point5}
Point2	1.201	0.8139
Point3		0.7159

This means we would combine Point3 with {Point1, Point2, Point5}. This leads to the following distance matrix. There is only one way to merge these which leads to the completion of the method (Gan, 120).

$$\begin{aligned}
D(\{Point1, Point3, Point4, Point5\}, Point2) \\
&= \text{Max}(D(\{Point1, Point4, Point5\}, Point2), D(Point3, Point2)) \\
&= \text{Max}(0.8139, 1.201) \\
&= 1.201
\end{aligned}$$

Table 2.12

Distance Matrix Complete Point {1,3,4,5}

Distance	{Point1,Point3, Point4, Point5}
Point2	1.201

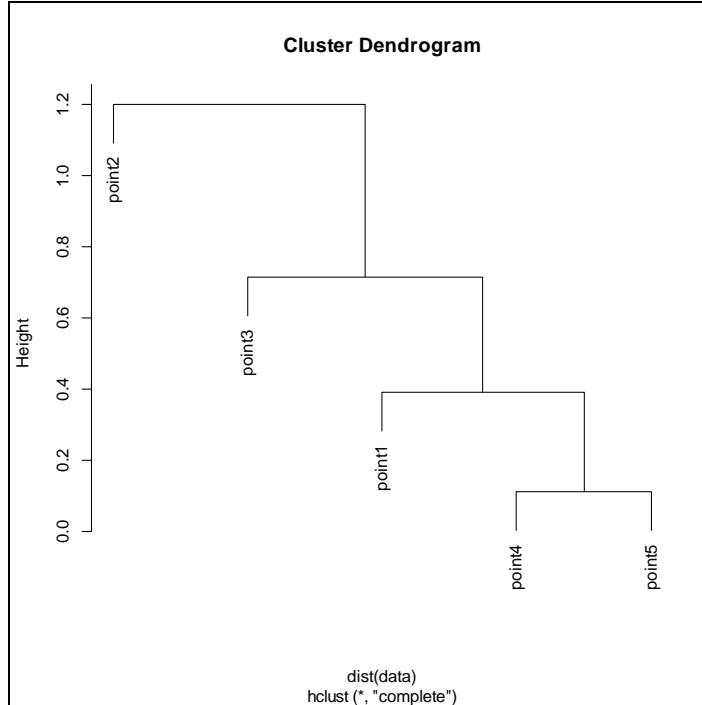

Figure 2.5. Dendrogram for the Complete Linkage Method.

2.5. Hierarchical Clustering with Median Linkage

Median method uses a different distance function than the other methods. In each step the distance between the new cluster and the other clusters is calculated as follows (Gan, 130).

Equation 2.3 Distance Function for the Median Method

$$D(C_k, C_i \cup C_j) = \frac{1}{2} D(C_k, C_i) + \frac{1}{2} D(C_k, C_j) - \frac{1}{4} D(C_i, C_j) \quad (2.3)$$

We first combine Point 4 and 5 since it is the smallest distance. Then calculate the distance from cluster {Point4, Point5} as follows.

$$\begin{aligned}
D(\{Point4, Point5\}, Point1) \\
&= \left(\frac{1}{2}\right) * (D(Point4, Point1) + D(Point5, Point1)) - \left(\frac{1}{4}\right) \\
&\quad * D(Point4, Point5) \\
&= \left(\frac{1}{2}\right) * (0.2828 + 0.3905) - \left(\frac{1}{4}\right) * 0.1118 \\
&= 0.3087
\end{aligned}$$

$$\begin{aligned}
D(\{Point4, Point5\}, Point2) \\
&= \left(\frac{1}{2}\right) * (D(Point4, Point2) + D(Point5, Point2)) - \left(\frac{1}{4}\right) \\
&\quad * D(Point4, Point5) \\
&= \left(\frac{1}{2}\right) * (0.7071 + 0.8139) - \left(\frac{1}{4}\right) * 0.1118 \\
&= 0.7326
\end{aligned}$$

$$\begin{aligned}
D(\{Point4, Point5\}, Point3) \\
&= \left(\frac{1}{2}\right) * (D(Point4, Point3) + D(Point5, Point3)) - \left(\frac{1}{4}\right) \\
&\quad * D(Point4, Point5) \\
&= \left(\frac{1}{2}\right) * (0.5025 + 0.4123) - \left(\frac{1}{4}\right) * 0.1118 \\
&= 0.4295
\end{aligned}$$

Which leads to the following distance matrix.

Table 2.13

Distance Matrix Median Point {4,5}

Distance	Point2	Point3	{Point4, Point5}
Point1	0.51	0.7159	0.3087
Point2		1.201	0.7326
Point3			0.4295

Since 0.3087 is the smallest distance we combine {Point4, Point5} with Point1 to form a new cluster. We then can calculate the distances to this newly formed cluster {Point1, Point4, Point5}.

$$D(\{Point1, Point4, Point5\}, Point2)$$

$$\begin{aligned} &= \left(\frac{1}{2}\right) * (D(\{Point4, Point5\}, Point2) + D(Point1, Point2)) \\ &\quad - \left(\frac{1}{4}\right) * D(\{Point4, Point5\}, Point1) \\ &= \left(\frac{1}{2}\right) * (0.7326 + 0.51) - \left(\frac{1}{4}\right) * 0.3087 \\ &= 0.5441 \end{aligned}$$

$$D(\{Point1, Point4, Point5\}, Point3)$$

$$\begin{aligned} &= \left(\frac{1}{2}\right) * (D(\{Point4, Point5\}, Point3) + D(Point1, Point3)) \\ &\quad - \left(\frac{1}{4}\right) * D(\{Point4, Point5\}, Point3) \\ &= \left(\frac{1}{2}\right) * (0.4295 + 0.7159) - \left(\frac{1}{4}\right) * 0.3087 \\ &= 0.4955 \end{aligned}$$

Table 2.14

Distance Matrix Median Point {1,4,5}

Distance	Point3	{Point1, Point4, Point5}
Point2	1.201	0.5441
Point3		0.4955

We combine {Point1,Point4,Point5} with Point3 to form a new cluster. Then we calculate the distance from cluster {Point1, Point3, Point4, Point5} to the other points as follows:

$$D(\{Point1, Point3, Point4, Point5\}, Point2)$$

$$= \left(\frac{1}{2}\right)$$

$$* (D(\{Point1, Point4, Point5\}, Point2) + D(Point3, Point2))$$

$$- \left(\frac{1}{4}\right) * D(\{Point1, Point4, Point5\}, Point3)$$

$$= \left(\frac{1}{2}\right) * (0.5441 + 1.201) - \left(\frac{1}{4}\right) * 0.4955$$

$$= 0.7487$$

The calculations agree with the dendrogram plot showing the hierarchy of the merging clusters.

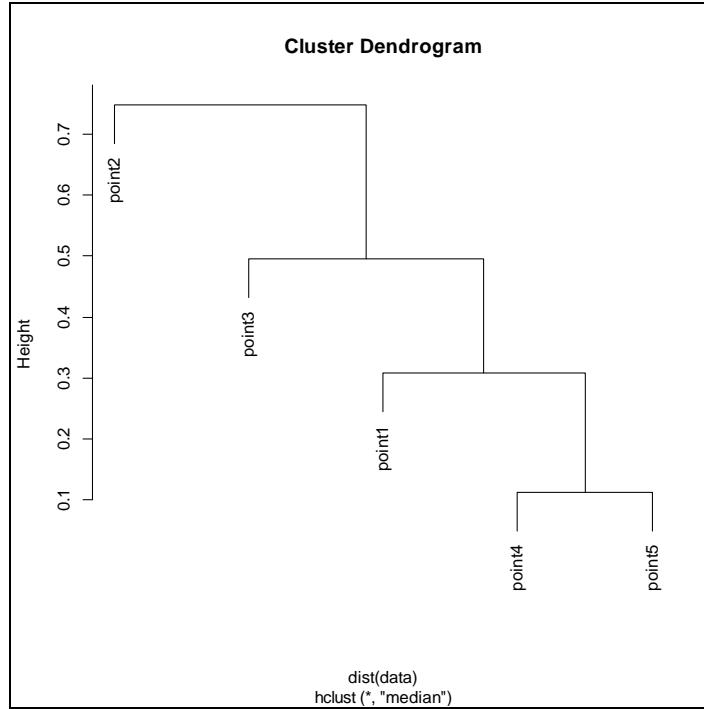

Figure 2.6. Dendrogram for the Median Linkage Method.

2.6. Hierarchical Clustering with McQuitty's Linkage

McQuitty's method is very similar to the average linkage with the exception that it doesn't keep taking the average. It keeps taking the middle of the two clusters that you want to combine (1966).

Equation 2.4 Distance Function for the McQuitty's Method

$$D(C_k, C_i \cup C_j) = \frac{1}{2} D(C_k, C_i) + \frac{1}{2} D(C_k, C_j) \quad (2.4)$$

First, we combine Point 4 and Point 5 into one cluster since they are the closest together. This then leads us to use the average distance when computing the next distance matrix. The distance between two points is then calculated as the average. Combine Point4 and Point5 since they are the shortest distance apart. We then have to calculate the distance from this cluster to the other points as follows:

$$\begin{aligned}
D(\{Point4, Point5\}, Point1) \\
&= \left(\frac{1}{2}\right) * (D(Point4, Point1) + D(Point5, Point1)) \\
&= \left(\frac{1}{2}\right) * (0.2828 + 0.3905) \\
&= 0.3367
\end{aligned}$$

$$\begin{aligned}
D(\{Point4, Point5\}, Point2) \\
&= \left(\frac{1}{2}\right) * D(Point4, Point2) + \left(\frac{1}{2}\right) * D(Point5, Point2) \\
&= \left(\frac{1}{2}\right) * 0.7071 + \left(\frac{1}{2}\right) * 0.8139 \\
&= 0.7605
\end{aligned}$$

$$\begin{aligned}
D(\{Point4, Point5\}, Point3) \\
&= \left(\frac{1}{2}\right) * D(Point4, Point3) + \left(\frac{1}{2}\right) * D(Point5, Point3) \\
&= \left(\frac{1}{2}\right) * 0.5025 + \left(\frac{1}{2}\right) * 0.4123 \\
&= 0.4574
\end{aligned}$$

Table 2.15

Distance Matrix McQuitty's Point {4,5}

Distance	Point2	Point3	{Point4, Point5}
Point1	0.51	0.7159	0.3367
Point2		1.201	0.7605
Point3			0.4574

After then combining Point 1 with Points 4 and 5, we then come up with a new distance matrix.

The calculations for this matrix are as follows:

$$D(\{Point1, Point4, Point5\}, Point2)$$

$$= \left(\frac{1}{2}\right) * (D(\{Point4, Point5\}, Point2) + D(Point1, Point2))$$

$$= \left(\frac{1}{2}\right) * (0.7605 + 0.51) = 0.6353$$

$$D(\{Point1, Point4, Point5\}, Point3)$$

$$= \left(\frac{1}{2}\right) * (D(\{Point4, Point5\}, Point3) + D(Point1, Point3))$$

$$= \left(\frac{1}{2}\right) * (0.4574 + 0.7159) = 0.5867$$

Table 2.16

Distance Matrix McQuitty's Point {1,4,5}

Distance	Point3	{Point1, Point4, Point5}
Point2	1.201	0.6353
Point3		0.5867

After the calculation combine Point 3 with Points 1, 4, 5. We have the following distance matrix:

$$D(\{Point1, Point3, Point4, Point5\}, Point2)$$

$$= \left(\frac{1}{2}\right) * (D(\{Point1, Point4, Point5\}, Point2)$$

$$+ D(Point3, Point2)) = \left(\frac{1}{2}\right) * (0.6353 + 1.201) = 0.9182$$

This agrees with the dendrogram which shows a visual of how the clusters were combined.

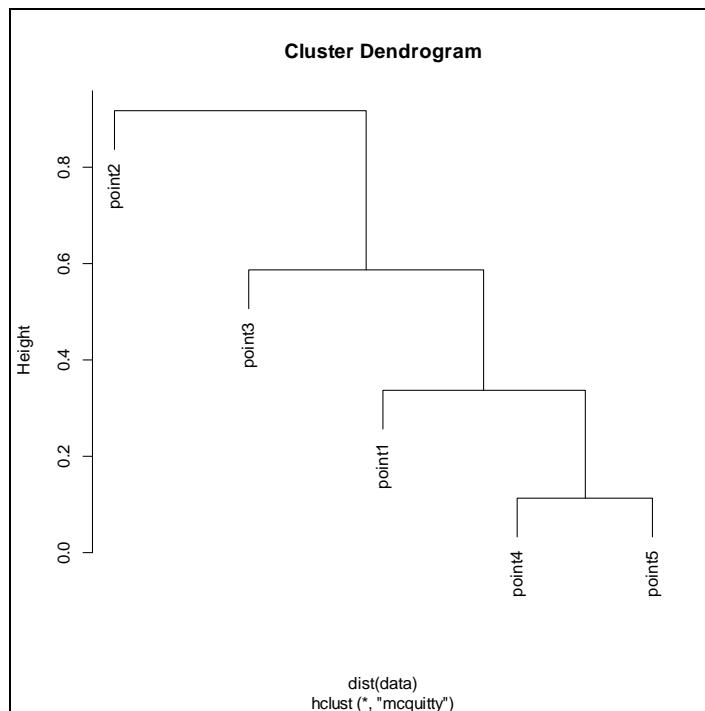

Figure 2.7. Dendrogram for the McQuitty's Linkage Method.

2.7. Hierarchical Clustering with Ward's Linkage

Ward's method is quite different from the other hierarchical clustering algorithms. As opposed to using a distance function and taking the smallest distance to combine into a new cluster, Ward's method minimizes the error sum of squares for each step (Gan, 132). This creates

a method that “minimizes variance.” Using Ward’s method there are three important equations to consider.

The first important equation is the distance function to combine clusters.

Equation 2.5 Distance Function for the Ward’s Method

$$\begin{aligned}
 D(C_k, C_i \cup C_j) &= \frac{|C_k| + |C_i|}{|C_k| + |C_i| + |C_j|} D(C_k, C_i) + \frac{|C_k| + |C_j|}{|C_k| + |C_i| + |C_j|} D(C_k, C_j) \\
 &\quad - \frac{|C_k|}{|C_k| + |C_i| + |C_j|} D(C_i, C_j)
 \end{aligned} \tag{2.5}$$

The other is the change in the error sum of squares. This first change in error sum of squares is to be calculated when there are no clusters, but just data points.

Equation 2.6 Change in Error Sum of Squares for Two Points

$$\Delta ESS_{ij} = \frac{1}{2} D(\text{Point } i, \text{Point } j)^2 \tag{2.6}$$

When there is at least one cluster, we change to the following equation for the change in error sum of squares:

Equation 2.7 Change in Error Sum of Squares for Two Clusters

$$\Delta ESS_{k(ij)} = \frac{1}{2} D(C_k, C_i \cup C_j) \tag{2.7}$$

First, the distance matrix must be squared. The purpose being Ward’s method minimizes the within group error sum of squares. Then, take the smallest squared distance which happens to be between Point 4 and Point 5.

$$ESS_1 = ESS_0 + \Delta ESS_{4,5} = \left(\frac{1}{2}\right) D(Point\ i, Point\ j)^2 = \left(\frac{1}{2}\right) * 0.1118 = 0.0559$$

We now have our first cluster, which consists of Point 4 and Point 5. We can now update the distance matrix.

$$D(\{Point4, Point5\}, Point1)$$

$$\begin{aligned} &= \left(\frac{2}{3}\right) * (D(Point4, Point1) + D(Point5, Point1)) - \left(\frac{1}{3}\right) \\ &\quad * D(Point4, Point5) \\ &= \left(\frac{2}{3}\right) * (0.08 + 0.1525) - \left(\frac{1}{3}\right) * (0.0125) \\ &= 0.1508 \end{aligned}$$

$$D(\{Point4, Point5\}, Point2)$$

$$\begin{aligned} &= \left(\frac{2}{3}\right) * (D(Point4, Point2) + D(Point5, Point2)) - \left(\frac{1}{3}\right) \\ &\quad * D(Point4, Point5) \\ &= \left(\frac{2}{3}\right) * (0.5 + 0.6625) - \left(\frac{1}{3}\right) * (0.0125) \\ &= 0.7708 \end{aligned}$$

$$D(\{Point4, Point5\}, Point3)$$

$$\begin{aligned} &= \left(\frac{2}{3}\right) * (D(Point4, Point3) + D(Point5, Point3)) - \left(\frac{1}{3}\right) \\ &\quad * D(Point4, Point5) \\ &= \left(\frac{2}{3}\right) * (0.2525 + 0.17) - \left(\frac{1}{3}\right) * (0.0125) \\ &= 0.2775 \end{aligned}$$

Table 2.17

Distance Matrix Ward's Point {4,5}

Distance	Point2	Point3	{Point4, Point5}
Point1	0.26	0.5125	0.1508
Point2		1.4425	0.7708
Point3			0.2775

The smallest value is between Point 1 and {Point 4, Point 5}. So, after combining into one new cluster, we have to recalculate the error sum of squares.

$$ESS_2 = ESS_1 + \Delta ESS_{451} = 0.0559 + \left(\frac{1}{2}\right) * 0.1508 = 0.1313$$

$$D(\{Point1, Point4, Point5\}, Point2)$$

$$\begin{aligned} &= \left(\frac{2}{4}\right) * D(Point1, Point2) + \left(\frac{3}{4}\right) * D(\{Point4, Point5\}, Point2)) \\ &\quad - \left(\frac{1}{4}\right) * D(\{Point4, Point5\}, Point1) \\ &= \left(\frac{2}{4}\right) * 0.26 + \left(\frac{3}{4}\right) * 0.7708 - \left(\frac{1}{4}\right) * 0.1508 = 0.6704 \end{aligned}$$

$$D(\{Point1, Point4, Point5\}, Point3)$$

$$\begin{aligned} &= \left(\frac{2}{4}\right) * D(Point1, Point3) + \left(\frac{3}{4}\right) * D(\{Point4, Point5\}, Point3)) \\ &\quad - \left(\frac{1}{4}\right) * D(\{Point4, Point5\}, Point1) \\ &= \left(\frac{2}{4}\right) * 0.5125 + \left(\frac{3}{4}\right) * 0.2775 - \left(\frac{1}{4}\right) * 0.1508 = 0.4267 \end{aligned}$$

Table 2.18

Distance Matrix Ward's Point {1, 4,5}

Distance	Point3	{Point1, Point4, Point5}
Point2	1.4425	0.6704
Point3		0.4267

$$ESS_3 = ESS_2 + \Delta ESS_{145} = 0.1313 + \left(\frac{1}{2}\right) * 0.4267 = 0.3447$$

Then the distances must be recalculated. So, the main idea is to keep calculating the error sum of squares and combine the clusters that minimize the error sum of squares.

$$\begin{aligned}
& D(\{Point1, Point3, Point4, Point5\}, Point2) \\
&= \left(\frac{2}{5}\right) * D(Point2, Point3) + \left(\frac{4}{5}\right) \\
&\quad * D(\{Point1, Point4, Point5\}, Point2) - \left(\frac{1}{5}\right) \\
&\quad * D(\{Point1, Point4, Point 5\}, Point3) \\
&= \left(\frac{2}{5}\right) * 1.4425 + \left(\frac{4}{5}\right) * 0.6704 - \left(\frac{1}{5}\right) * 0.4267 = 1.0280
\end{aligned}$$

Table 2.19

Distance Matrix Ward's Point {1,3,4,5}

Distance	{Point1, Point3, Point4, Point5}
Point2	1.0280

Then the entire cluster merging has been completed, but the last calculations are as follows.

$$ESS_4 = ESS_3 + \Delta ESS_{1345|2} = 0.3447 + \left(\frac{1}{2}\right) * 1.0280 = 0.8587$$

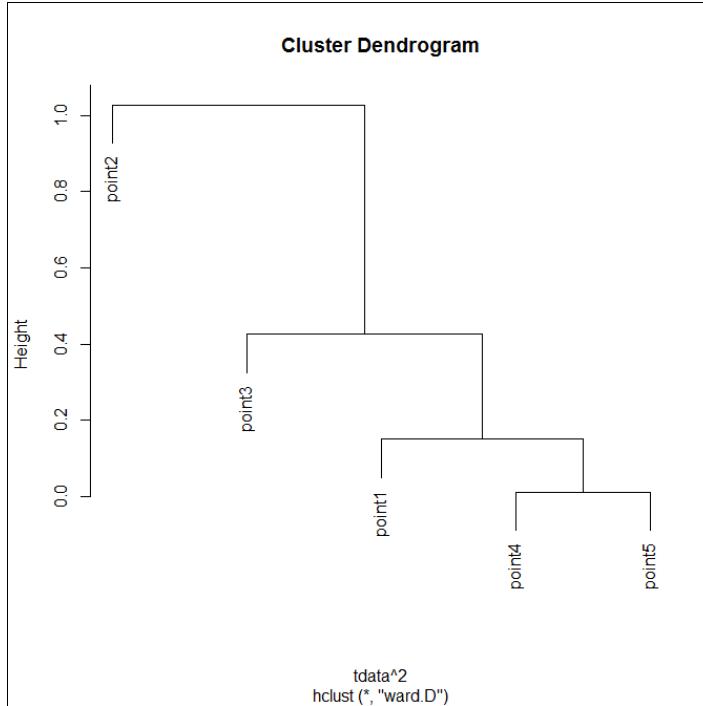

Figure 2.8. Dendrogram for the Ward's Linkage Method.

The dendrogram agrees with the calculations.

2.8. K-means Clustering Algorithm

K-means is an iterative algorithm that needs the number of clusters specified in order to run. The main idea behind k-means is the initialization phase. For this phase you decide how many clusters you are trying to separate the data into. Let's say you are trying to assign the data into k clusters. First, choose k points at random without replacement. Then the iteration phase happens, in this phase you assign each point to the cluster that it is closest to. Then you recalculate the means for each cluster. With this new mean, you then assign each point to the closest cluster. This process is then repeated until there are no changes in the classification of the cluster. There is a possibility that this algorithm will never converge. For those cases, it is

recommended to specify a maximum iteration. This will assure you will not be searching forever.

Then you can just restart the initialization phase again and try again with k new points.

Applying this to the previous example, assume you are trying to cluster data into 2 clusters. K-means randomly chooses 2 different points. From these two points each other point is assigned to be in the cluster that is closest to the randomly chosen points. After each point has been assigned to a cluster the means are recalculated. The points are again assigned to the cluster with the closest point. For example, let's choose 2 points at random from our example. Without loss of generality, we chose Point 1 and Point 3. We then choose these values as our clusters. At that point we assign every other point to the closest cluster. Point 2 will be assigned to cluster 1 which consists of Point 1. Point 4 will be assigned to cluster 1 since it is closer. Point 5 will be assigned to cluster 1. Cluster 1 consists of Point 1, Point 2, Point 4 and Point 5. The second cluster consists of just Point 3. The mean is then recalculated for each cluster. Adding up all the x values for cluster 1, we get 7.55. Dividing by 4, we get an average x of 1.8875. Adding up all the y values for cluster 1, we get 10. Dividing by 4, we get an average y value of 2.5. So, we now have centers of clusters at (1.8875, 2.5) and (1.9, 1.8). All of the points are assigned to cluster 1 and cluster 2 consists of its only point. This process can happen very quick or sometimes not at all (Gan, 162).

2.9. PAM Clustering Algorithm

PAM stands for Partition Around Medoids. The clustering algorithm is very similar to K-means. There is just a few slight differences. The process for PAM is to first choose k points at random. These k points are considered to be the medoid. For each medoid assign each data point to the closest medoid. For each cluster, calculate the total cost. The total cost is defined as the sum of all of the distances from the medoid for that particular cluster. Then calculate the cost of

swapping a medoid. This means the replacement one of your medoids with another point. The reasoning is that maybe another medoid will result in a lower total cost. This process of assigning points to the medoid then calculating the cost of swapping is repeated until there is no change in the medoid (Kaufman, 68).

For example consider 2 clusters for the example data. If we again randomly chose two points and choose Point 4 and Point 5 for the medoid. From these two medoids, we need to calculate the cost (Euclidean distance). We then end up with two tables. Let's assume cluster 1 is Point 4 and cluster 2 is Point 5

Table 2.20

Cost Matrix For PAM

Point	Cost to Point 4	Cost to Point 5	Assign
Point 1	0.2828	0.3905	Cluster 1
Point 2	0.7071	0.8139	Cluster 1
Point 3	0.5025	0.4123	Cluster 2
Point 4	Medoid		
Point 5		Medoid	

From these two starting medoids, we will then assign {Point 1 and Point 2} to cluster 1. We will then assign {Point 3} to cluster 2. We then calculate the total cost. This is the sum of the distances for each point to the cluster medoid.

$$\text{cluster1 total cost} = 0.2828 + 0.7071 = 0.9899$$

$$\text{cluster2 total cost} = 0.4123$$

$$\text{total cost} = 0.9899 + 0.4123 = 1.4022$$

Let's consider swapping Point 4 with Point 2.

Table 2.21

Cost Matrix For Swapping Points PAM

Point	Cost to Point 2	Cost to Point 5	Assign
Point 1	0.51	0.3905	Cluster 2
Point 2	Medoid		
Point 3	1.201	0.4123	Cluster 2
Point 4	0.7071	0.1118	Cluster 2
Point 5		Medoid	

$$\text{cluster1 total cost} = 0$$

$$\text{cluster2 total cost} = 0.3905 + 0.4123 + 0.1118 = 0.9146$$

$$\text{total cost} = 0 + 0.9146 = 0.9146$$

There was a significant improvement to the total cost by using Point 2 as opposed to Point 4. This process of swapping and then recalculating the cost is repeated until there is no more improvement.

Average pairwise overlap is used because it is a measure of the level of difficulty in separation between clusters. Clusters that have a significant level of overlap are going to be harder to distinguish. Overlap between two clusters is the sum of misclassification probabilities (Maitra, 354-376).

Some sort of measure needs to be used in order to compare the cluster's performance in its ability to classify. The Rand Index is a measure of how well the clusters agree with each other. It is a measure of how well two different classifications agree or disagree with each other. One flaw about the Rand Index is that it does not take into consideration the number of clusters; therefore, the Adjusted Rand Index is a better measure for performance of classification.

The Rand Index can be calculated by first creating a table of the classification of clusters.

Let X be a set of n data points $\{x_1, x_2, \dots, x_n\}$. Consider two different clustering classifications of the data points with the number of clusters equal to C. Let V denote the first classification vector of the data points $\{V_1, V_2, \dots, V_C\}$. Let U denote the classification vector of the data points $\{U_1, U_2, \dots, U_C\}$. A table is created to reflect the number of agreements between the two different clustering classifications. The table would look similar to the following (Yeung).

Table 2.22

Classification Table for Clusters

	V1	V2	...	VC	RowSum
U1	n_{11}	n_{12}	...	n_{1C}	$n_{1.}$
U2	n_{21}	n_{11}	...	n_{2C}	$n_{2.}$
...
UC	n_{C1}	n_{C2}	...	n_{CC}	$n_{C.}$
ColSum	$n_{.1}$	$n_{.2}$...	$n_{.C}$	TotalSum = n

$n_{ij} = \text{the number of agreements between } U_i \text{ and } V_j$

$$n_{.j} = \sum_{i=1}^C n_{ij}$$

$$n_{i.} = \sum_{j=1}^C n_{ij}$$

From this classification table, we calculate a summary of agreement and disagreements.

Equation 2.8 Number of Agreements

$$a = \sum_{ij} \binom{n_{ij}}{2} \quad (2.8)$$

Equation 2.9 Number of Objects in the same cluster for U but not in the same class in V

$$b = \sum_i \binom{n_{i.}}{2} - \sum_{ij} \binom{n_{ij}}{2} \quad (2.9)$$

Equation 2.10 Number of Objects in the same cluster for V but not in the same class in U

$$c = \sum_j \binom{n_{.j}}{2} - \sum_{ij} \binom{n_{ij}}{2} \quad (2.10)$$

Equation 2.11 Number of Disagreements

$$d = \binom{n}{2} - a - b - c \quad (2.11)$$

Equation 2.12 Formula for the Rand Index

$$RI = \frac{a + d}{a + b + c + d} \quad (2.12)$$

Equation 2.13 Formula for the Adjusted Rand Index

$$ARI = \frac{\sum_{ij} \binom{n_{ij}}{2} - \frac{\sum_i \binom{n_{i.}}{2} \sum_j \binom{n_{.j}}{2}}{\binom{n}{2}}}{\frac{1}{2} [\sum_i \binom{n_{i.}}{2} + \sum_j \binom{n_{.j}}{2}] - \frac{\sum_i \binom{n_{i.}}{2} \sum_j \binom{n_{.j}}{2}}{\binom{n}{2}}} \quad (2.13)$$

The Adjusted Rand Index is a measure of how well the clustering classification is done. It is bounded above by 1, but has no lower bound for the index. The benefit of the Adjusted Rand Index over the Rand index is that it has an expected value of 0. The Rand Index has an expected

value of something greater than 0 and less than 1. It is a measure that is not constant. This is a big draw back when comparing clusters because you do not know how good the clustering algorithm is relative to chance.

CHAPTER 3. METHODOLOGY

The purpose of this study is to compare 10 different clustering algorithms. The clustering algorithms used were PAM, K-means, and hierarchical clustering algorithms. The hierarchical clustering link functions used were Wards, Single, Complete, Average, McQuitty, Median, and Centroid. With this study, we will be able to conclude the best and worst clustering algorithms. The complexity in the data is from the number of dimensions (2, 5, 10), number of clusters (4, 8, 16), pairwise average overlap between the clusters (0.001, 0.005, 0.01, 0.05, 0.1, 0.2), and the average number of points simulated from each cluster (10, 25, 100). From these data, it will be repeated 1000 times. We did not simulate more repetitions, due to time constraints.

The data factors important in a simulation study are the type of data and how the data were simulated. We used Clustering Algorithms' Referee Package (CARP), which is a C-package that is quite easy to implement in Linux. The reasoning behind using CARP is that it is very efficient; the layout is very easy to use and understand. The idea is to simulate mixture distributions with a certain condition; then simulate data from the mixtures. After the data has been simulated, the clustering algorithms will be used on each specific data set. The clustering algorithm will tell which data points are in each cluster. Since it is known where each data point is simulated from; we can gauge the accuracy of the clustering algorithm. Next, a pairwise comparison will be implemented to see how the clustering algorithms perform amongst each other.

First, the mixtures must be simulated. This is one of the most important parts of a simulation study. It is important because if the data being simulated does not have a significant amount of meaning, the results will have little impact in their importance. Different clustering algorithms are known to perform better under different situations. There is no known guide of

when to use a particular clustering algorithm. Since Gaussian data is the most common; it would make sense to test different clustering algorithms using Gaussian data. While using a Gaussian mixture data with a pre-specified average pairwise overlap and number of dimensions, we simulate the mixtures. This is accomplished with the command:

```
./CARP -G4 -p2 -b0.05 -#1000
```

The **-G** in the command specifies the number of mixing components. This command simulates a mixture with 4 mixing components. The **-p** in the command specifies the number of dimensions. This command specifies a 2 dimensional space. The **-b** in the command is the pairwise average overlap. The **-#** section of the command specifies how many mixtures you want. In this case, we would like 1000 different mixture distributions with a pairwise overlap of 0.05, the number of dimensions equal to 2, and the number of mixing components equal to 4.

From this mixture, we can simulate data from the Gaussian mixtures. In order to make the problem a little more complex, we will simulate a small (approximately 10 points), medium (approximately 25), and large (approximately 100 points) number of points from each cluster. Since this is simulated, the mixing proportions will be used as weights for the number of points simulated. For example, consider a mixture which has the mixing proportions of (1/4, 3/4), the majority of the mixture is composed from the second component. We would like most of the points to come from the second component of the mixture. One way to accomplish this is to set this up a Bernoulli with a proportion of success equal to 1/4. The randomness of which mixing component the data point comes from is then preserved. This process is repeated until you have the desired number simulated data points. The data is simulated with a command:

```
./CARP -G4 -p2 -#1000 -n40
```

The only difference is now we do not have to specify the average overlap like we did in the previous command. Instead, we specify the average number of data points simulated from each mixture. From this statement, we get 1000 data sets composed of 2 dimensional Gaussian data with 4 mixing components with approximately 40 points from each mixing component.

Now that the data is simulated, we can run each of the clustering algorithms on the dataset. This is accomplished with the command:

```
./CARP -G4 -p2 -#1000 -n-40 -Rhierclust1.dat -Ahierclust1
```

The – between the n and the 40 represents data that have already been simulated. This indicates there is already 40 data points simulated and not to simulate new data. The –R is to output the Adjusted Rand Index. We specify this because we can then run each different clustering algorithm on the same set of data and output only the adjusted rand. The –A part of this command specifies which clustering algorithm is used. After repeating this for each different clustering algorithm, we can compare Adjusted Rand indices from each clustering method. Comparison is done using a two sample t-test.

In R: `t.test(Hierclust1, Hierclust2)`

Where Hierclust1 and Hierclust2 are the Adjusted Rand indices from the clustering algorithms used.

From the Adjusted Rands, we can figure the mean to determine the best to worst performing clustering algorithm. We then created a matrix of p values from the pairwise comparisons. One example of this would be:

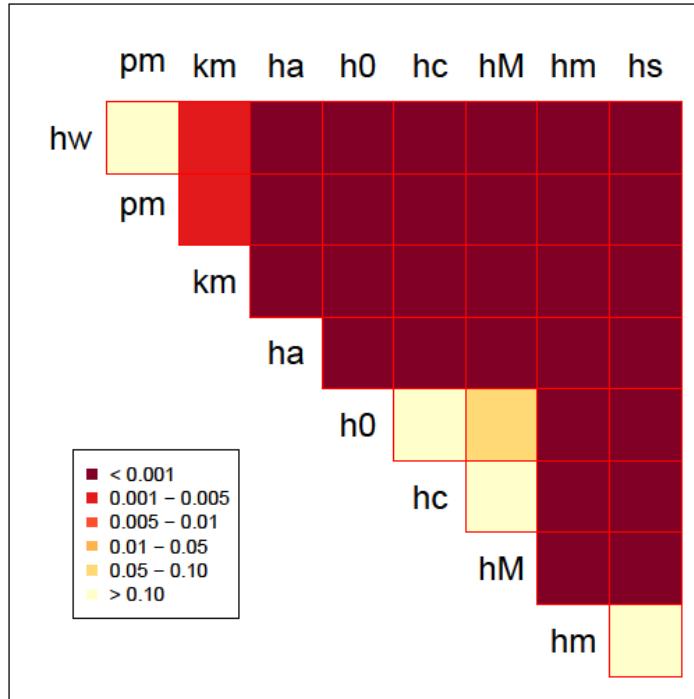

Figure 3.1. Four Cluster 2 Dimension 0.001 Average Pairwise Overlap with 40 Points.

As you can see, this is made into a format that is easy to understand. Each of the two letters would be the specific clustering algorithm. The heat map shows the p value. If the color is white or cream, there is no significant difference between the two clustering algorithms. Whereas, if the color is not cream there is a significant difference between the two clustering algorithms. This heat map is then repeated for all the different combinations of dimensions, clusters, average pairwise overlap, and average number of elements in each cluster.

CHAPTER 4. RESULTS

4.1. Four Cluster Results

The results are quite interesting (see Appendix A). As you move from very little pairwise overlap to substantial pairwise overlap, you would think that the best clustering algorithm may differ. Looking at the results, it is the same three clustering algorithms that perform as the top three for all of the 4 cluster results. Dimensions had no effect on change the results of the best three clustering algorithms. An interesting result happens when considering the 2 dimensional space (Appendix A, Figures A.1-A.18). The clustering algorithm PAM (Partitioning Around Medoids) performs the best for most cases. There is one case when a hierarchical with Ward's linkage performs significantly better than PAM (see Figure A.3).

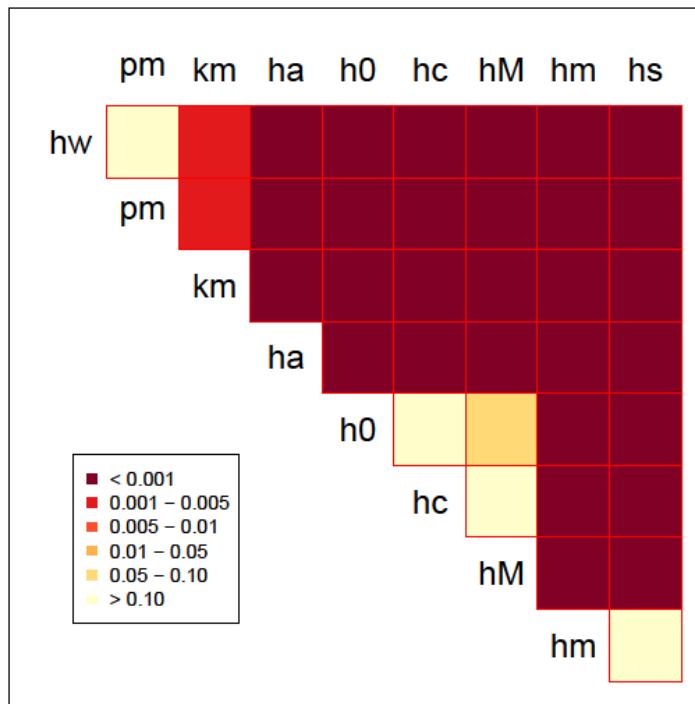

Figure 4.1. Four Cluster 2 Dimension 0.001 Average Pairwise Overlap with 40 Points.

Figure 4.1 is an example of how every specific case of number of clusters, dimension, average pairwise overlap, and number of points simulated have been summarized. There are nine different abbreviations for the clustering algorithms which are illustrated in Table 4.1.

Table 4.1

Abbreviations of the Clustering Algorithms

Abbreviation	Clustering Algorithm
hw	Hierarchical with Ward's linkage
hs	Hierarchical with Single linkage
hc	Hierarchical with Complete linkage
ha	Hierarchical with Average linkage
hM	Hierarchical with Mc Quitty's linkage
hm	Hierarchical with Median linkage
h0	Hierarchical with Centroid linkage
pm	Partition Around Medoids (PAM)
km	K-means

The clustering algorithms are sorted by the mean. Taking the average of all of the adjusted Rand values for each different clustering algorithm, we can tell which performs the best. In order to do a comparison to see which clustering algorithms are statistically significant, a t-test will show a pairwise comparison of two clustering algorithms. T-tests are then repeated for all pairwise comparisons for each specific cluster, dimension, pairwise overlap, and number of points simulated. In Figure 4.1 there are 36 different squares with each square representing a t-test. The t-test is a comparison of all 1000 adjusted rand values for the two clustering algorithms being compared in that particular square. The different colors in each square represent the p value for the t-test. If the color is cream the p value for the t-test is greater than 0.10. This means

there is no significant difference between the two algorithms being compared for that particular square. If the color is slightly darker than cream it represents a p value inside the interval (0.05, 0.10). This would mean the two algorithms are not considered to be significantly different at an alpha level of 0.05. If the color has any shade of red, it represents a p value of less than 0.05. This would indicate that the two clustering algorithms are significantly different. The darker the shade of red, the more significant the p value would be.

One clustering algorithm that tied with PAM would be hierarchical with Ward's linkage. This happened in 5 of the 18 cases, which mostly occurred when the average pairwise overlap was small (less than 0.005). The other clustering algorithm that tied with PAM was K-means. This algorithm tied in 3 of the 18 cases. This also happened when the average pairwise overlap was large (0.05, 0.1, 0.2) and when there was only a total of 40 points simulated. It was also interesting that it did not typically matter how many points were simulated from each cluster. One might think that if you have more points from each cluster that the results may differ; this was not true in the 4 cluster results.

While increasing the dimensions to 5 and 10 a new clustering algorithm emerged as the best performer; K-means performed the best for the majority of the dimensions equal to 5. There was one case (see Figure A.21) in which a hierarchical with Ward's linkage performed the best. For all other cases, K-means was the best or not significantly different from the best performing clustering algorithm. The results for the 5 dimensional space can be found in Appendix A, Figures A.19-A.36. When the dimensions were increased to 10, the results did not change much from the 5 dimension space. In the 10 dimension space, K-means performed the best in all 18 cases (Figures A.37-A.54).

4.2. Eight Cluster Results

When the dimension fixed at 2, PAM performs the best for all cases. The results for the 8 cluster 2 dimension space can be found in Appendix B, Figures B.1-B.18. There are seven cases where three different algorithms performed with no significant difference than PAM. The other three algorithms are K-means, hierarchical with Ward's linkage, and hierarchical with Average linkage. When the average pairwise overlap is 0.001 hierarchical with Ward's linkage the calculation performed the same as PAM for the number of points simulated equal to 200 and 800 (Figures B.2-B.3). When the average pairwise overlap was 0.01 Ward's linkage also tied with PAM though this was only in the case where the number of points simulated was 80 (Figure B.7). There were two cases where all three (PAM, K-means, and hierarchical with Ward's linkage) algorithms performed similarly to each other. These cases occurred when the number of points simulated was 80 and the average pairwise overlap was 0.05 and 0.1 (Figures B.10 and Figure B.13). This outcome was kind of a surprise since one would expect that when the average pairwise overlap is low, all the clustering algorithms would perform well. The powers of all the algorithms are high, but these three algorithms have the highest average adjusted Rand values.

When the average pairwise overlap was 0.2 and the number of points simulated equal to 80 and 200, K-means performs similarly to PAM (Figures B.16-B.17). When considering the number of dimensions equal to 5 (Figures B.19-B.36) and 10 (Figures B.37-B.54), K-means generally performed the best. There are three cases when K-means is outperformed by another algorithm. These three cases occur when the average pairwise overlap is 0.001 and the number of points simulated is 80, 200, and 800 (Figures B.19-B.21). The clustering algorithm that performs the best for these three cases is hierarchical with Ward's linkage. Also, for these three cases, PAM is shown to perform better than K-means. There are also two cases where hierarchical with

Ward's linkage is shown to perform similarly to K-means. These two cases are when the average pairwise overlap is 0.005 and the number of points simulated is 200 and 800 (Figures B.23-B.24). With the exception of those few cases K-means seems to have greater powers for 5 and 10 dimensions than the other algorithms.

4.3. Sixteen Cluster Results

The results for 16 were the most unique. When the number of dimensions was 2, PAM performed the best overall (see Figures C.1-C.18). There were five cases that PAM was tied for the best algorithm. One of these occurred when the average pairwise overlap equal to 0.01 and the number of points simulated equal to 160 (Figure C.7). In this case, PAM tied with hierarchical with Ward's linkage. When the average pairwise overlap was equal to 0.05 and the number of points simulated was 160 there were three algorithms tied for the best (Figure C.10). The three algorithms were PAM, K-means, and hierarchical with Ward's linkage. There was also a three way tie that occurred when the number of points was equal to 160 and the average pairwise overlap was 0.1 and 0.2 (Figures C.13 and C.16). When the number of dimensions equal to 5, K-means performs the best overall (see Figures C.19-C.36). When the average pairwise overlap is 0.001 and 0.005, hierarchical with Ward's linkage performs the best (see Figures C.19-C.21 and C.22-C.24). Increasing the average pairwise overlap beyond 0.005 K-means performs the best for the remainder of the situations where there are 5 dimensions (see Figures C.25-C.36). After increasing the dimensions to 10, K-means performs the best for all levels of average pairwise overlap (see Figures C.37-C.54).

CHAPTER 5. SUMMARY AND CONCLUSIONS

When considering only the 4 cluster 2 dimensional cases, PAM performs the best. There was one case when hierarchical with Ward's linkage performed better than PAM, this particular case was when the average pairwise overlap was 0.001 and the number of points simulated was 400. Considering dimensions higher than 2, K-means performed the best overall. There were two cases in the 5 and 10 dimensions when another algorithm tied with K-means. One particular case was when the dimension was 5 and the average pairwise overlap was 0.001 and the number of points simulated was 100. The second case was when the dimension was 5 and average pairwise overlap was 0.005, the number of points simulated 400. In both of these cases hierarchical with Ward's linkage was the algorithm that tied K-means. For all cases of the 5 and 10 dimension space K-means performed the best. There cannot be an overall best for the 4 cluster case. It seems that it is more dependent on the number of dimensions since PAM performed the best for the 2 dimensional cases and K-means performed the best for the 5 and 10 dimensional cases.

When fixing the number of clusters at 8 and the number of dimensions to 2, PAM performs the best for all cases. Increasing the dimension to 5 there were 2 algorithms that performed the best. When the average pairwise overlap was very little at 0.001, hierarchical with Ward's linkage performed the best. Increasing the average pairwise overlap to 0.005 and higher K-means performed the best overall. There were a few cases where hierarchical with Ward's linkage was tied with K-means. Those cases occurred when the average pairwise overlap was 0.005 and the number of points simulated was 200 and 800. Fixing the dimension to 10, K-means performed the best for all cases of average pairwise overlap and number of points simulated.

When fixing the number of clusters at 16 and the number of dimensions to 2, PAM performed the best for all cases. When increasing the number of dimensions to 5, there were mixed results again similar to the 8 cluster case. When the average pairwise overlap was 0.001 and 0.005, hierarchical with Ward's linkage performed the best. Increasing the pairwise overlap to 0.01, K-means performed the best. Increasing to 10 dimensions and fixing the average pairwise overlap to 0.001, hierarchical with Ward's linkage performed the best. Increasing the average pairwise overlap to 0.005 and greater, K-means performed the best.

In conclusion, some of the factors that were thought to add complexity to the clustering algorithm results, did not change the results as expected. One would have assumed that with low pairwise overlap, all of the clustering algorithms would do quite well. If one increased the pairwise overlap, it would seem that a distance measure that uses the median might perform better. Increasing the number of clusters from 4 to 8 to 16, it would seem that as there are more clusters that Ward's might perform the best since it minimizes the total within-cluster variance. When increasing the average number of points from each cluster from 10 to 25 to 100, it would seem that the clusters would be better represented and the mean would turn into the best method. Some of these generalizations have turned out to be true, but a lot of them in fact were not. The main factor turned out to be the number of dimensions, regardless of the pairwise overlap, number of points simulated, and number of clusters. This is quite surprising because given the dimension there is a best performing clustering algorithm. The results conclude that if there are 2 dimensions, PAM performs the best. If the number of dimensions are 5 or 10, K-means performs the best. There were a few cases where these algorithms did not perform as well. As an overall best-clustering algorithm these two algorithms would be the choice.
